

The economy as a constraint satisfaction problem

Dhruv Sharma, Jean-Philippe Bouchaud, Marco Tarzia, Francesco Zamponi

Laboratoire de Physique-Ecole Normale Supérieure, Ecole Polytechnique

International Conference on Complex Systems

27th July 2020

- Beyond the DSGE framework
- Construct true “micro-founded” models.
- Agents are given some behavioral rules and then we simulate each agent’s behavior
- Agents are only boundedly rational: no infinite horizon utility maximization.

Summary figure Schematic of the typical elements of an agent-based model

From Turrell (2016)

Constraint satisfaction problems

- Economic actors have to face all sorts of constraints: budget, leverage etc.
- Make agents' behavior depend on these constraints.
- CSPs like K-SAT, q-coloring or perceptron

Perceptron to the market

M agents (μ), N goods (i)

For each agent

Generic "demand" ξ_i^μ

$\xi_i^\mu > 0$ sell product i

$\xi_i^\mu < 0$ buy product i

For each good

Price of good i p_i

$$\frac{1}{N} \sum_i^N p_i = 1$$

Positivity $\forall i \ p_i \geq x_m$

Money exchanged

Budget

$$\frac{1}{\sqrt{N}} \sum_i \xi_i^\mu p_i \geq \sigma$$

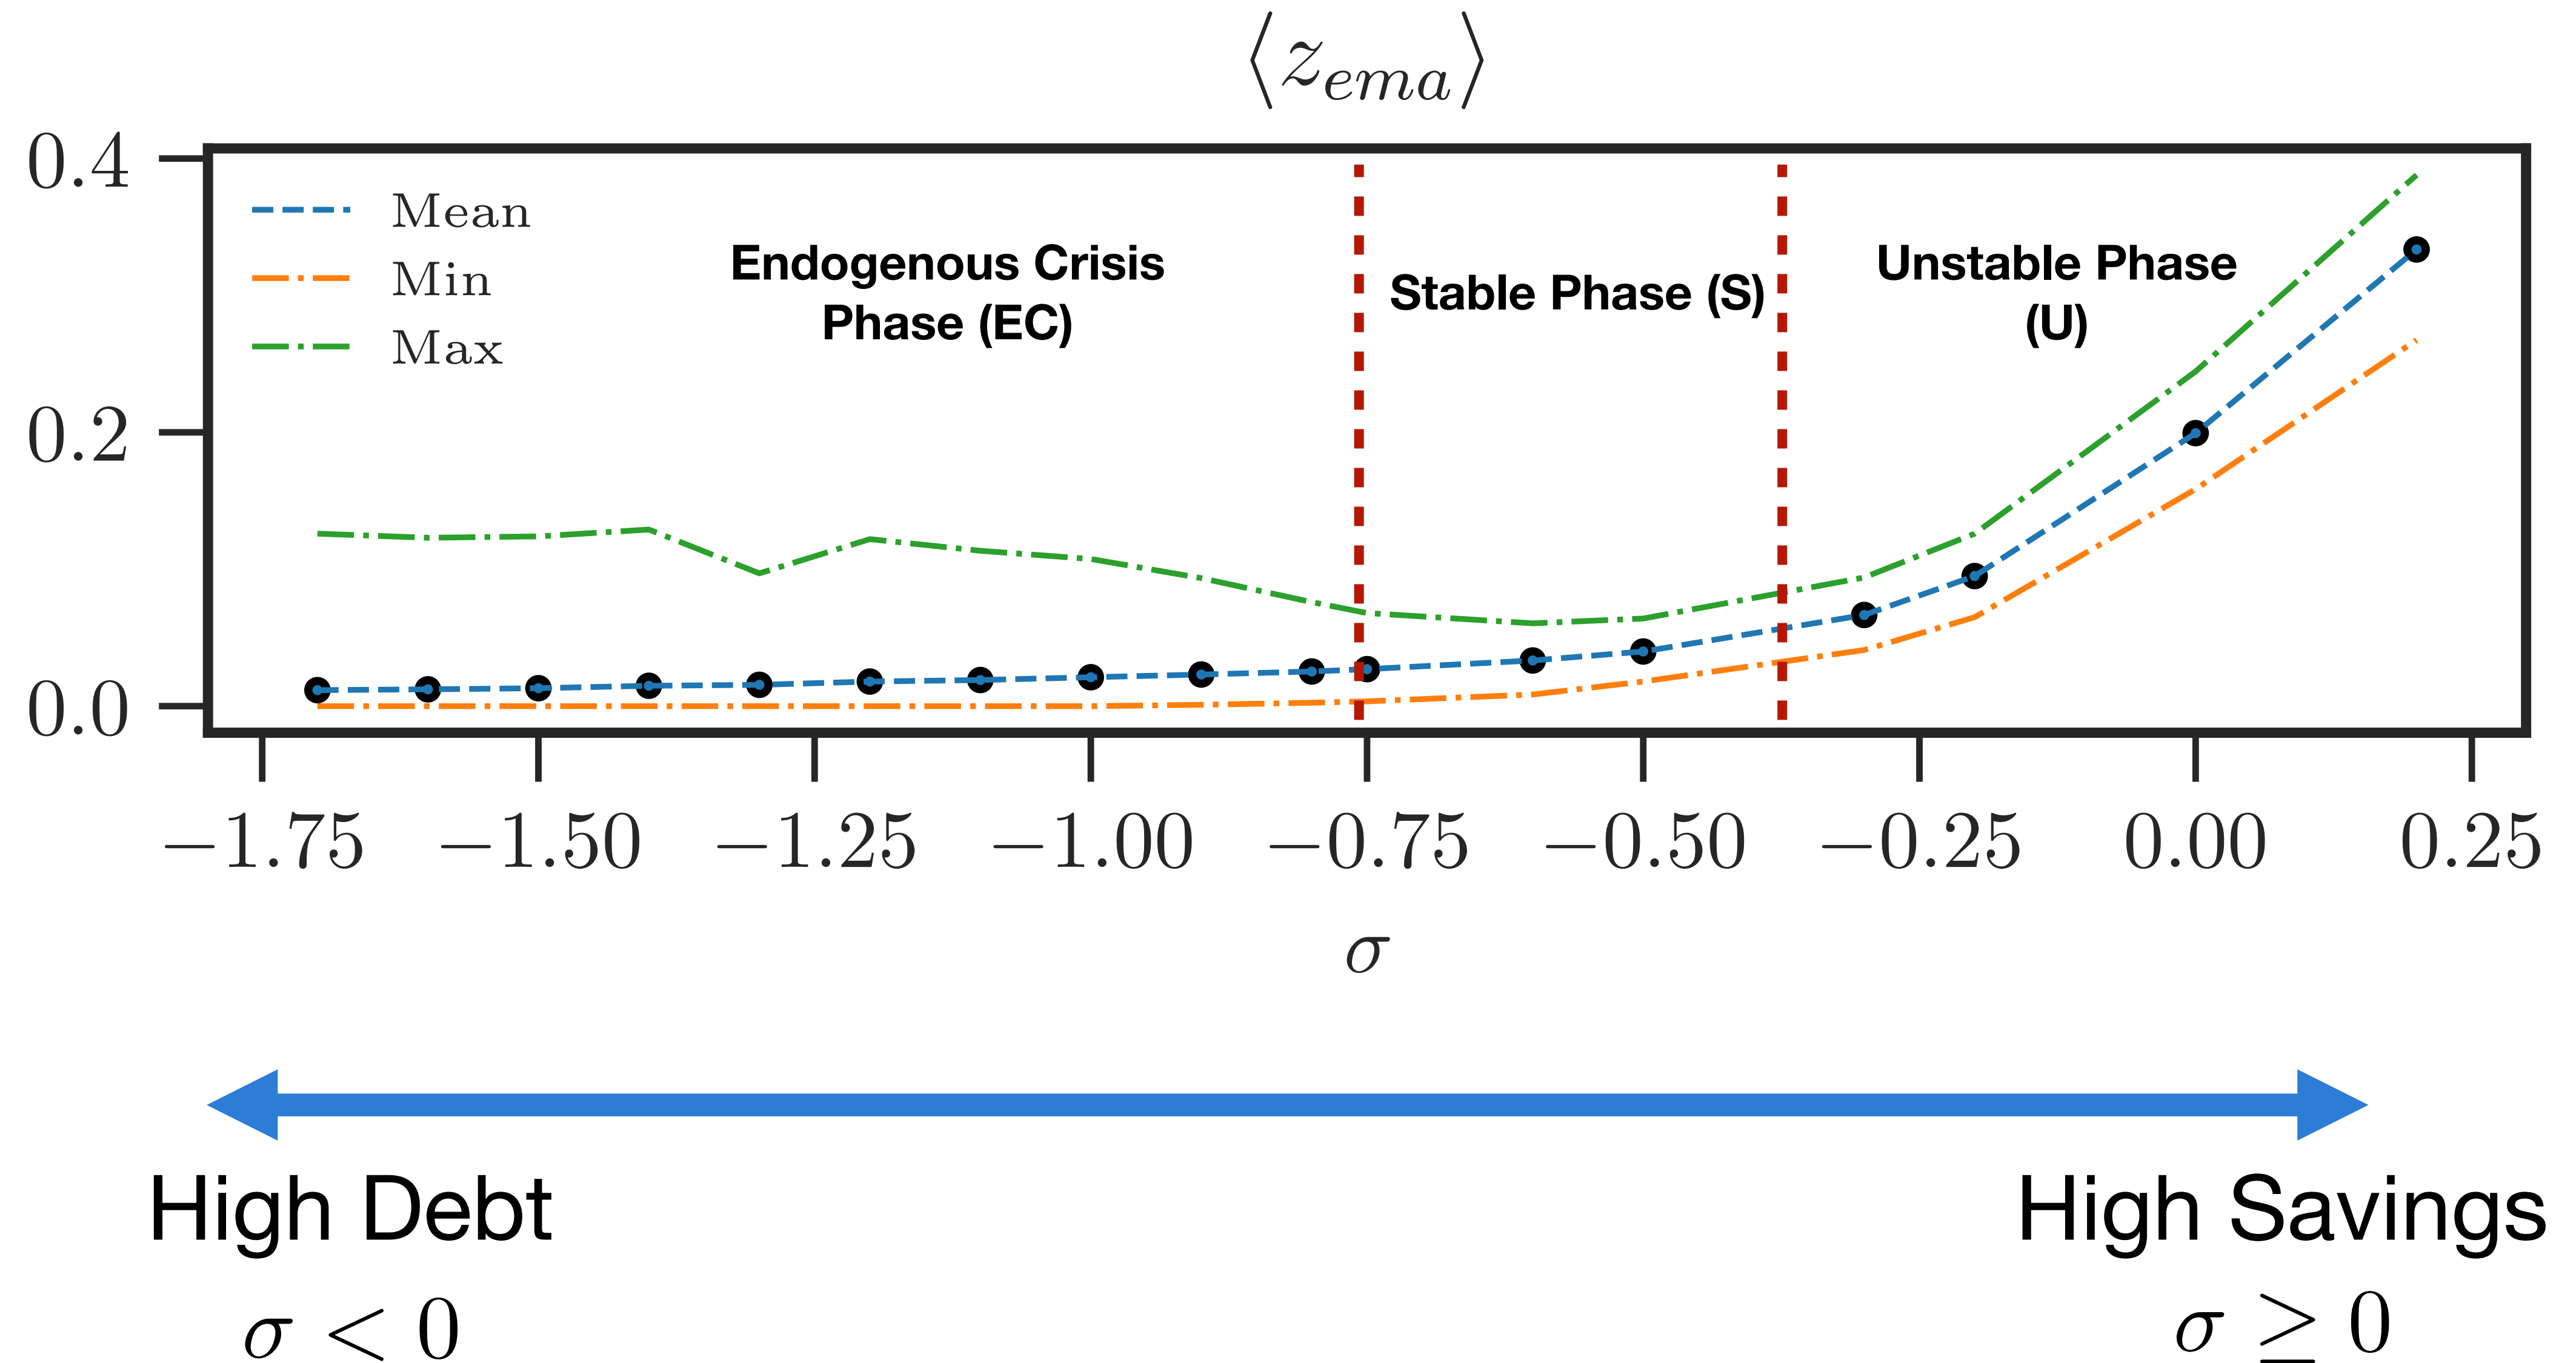

$\sigma < 0$ Money borrowed

$\sigma \geq 0$ profit / savings

For standard perceptron ξ_i^μ Input patterns p_i Synaptic Weights

1. Update preferences heuristically:
 - If Supply $>$ Demand, suppliers reduce production
 - If Goods are expensive, consumer reduce consumption.
2. Find prices that satisfy most agents by optimising a cost function
3. Transactions and Redistribution.
4. Remove agent if budget constraints violated for multiple time steps.

Rate of Bankruptcies

Dynamically

High Debt

$$\sigma < 0$$

**Endogenous Crisis
Phase (EC)**

Stable Phase (S)

**Unstable Phase
(U)**

High Savings

$$\sigma \geq 0$$

Prices vs Supplies (Demands)

Endogenous Crisis Phase (EC)

$$\sigma = -1.6$$

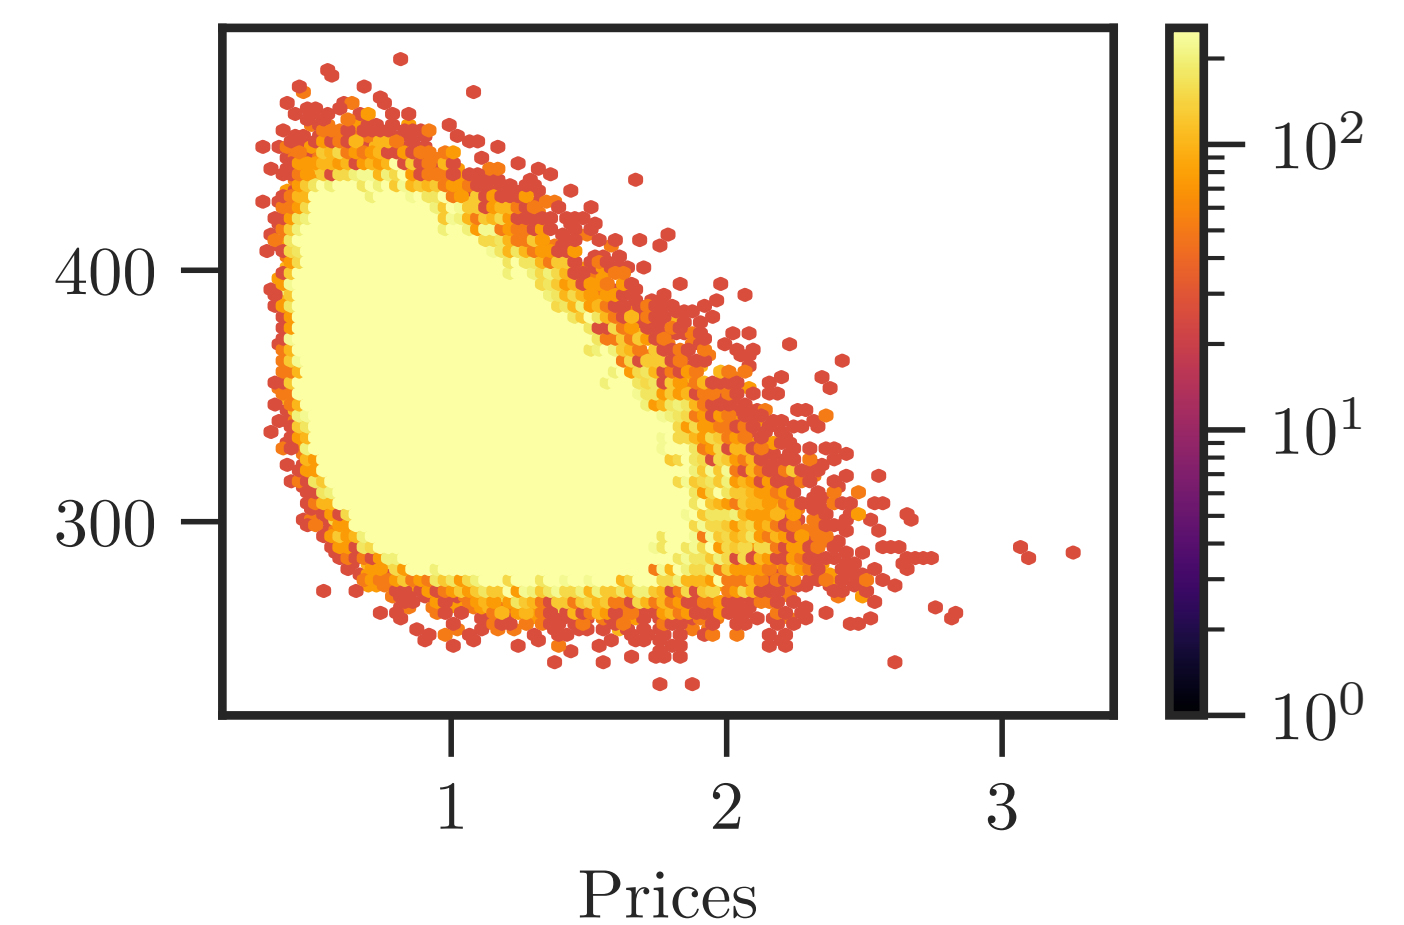

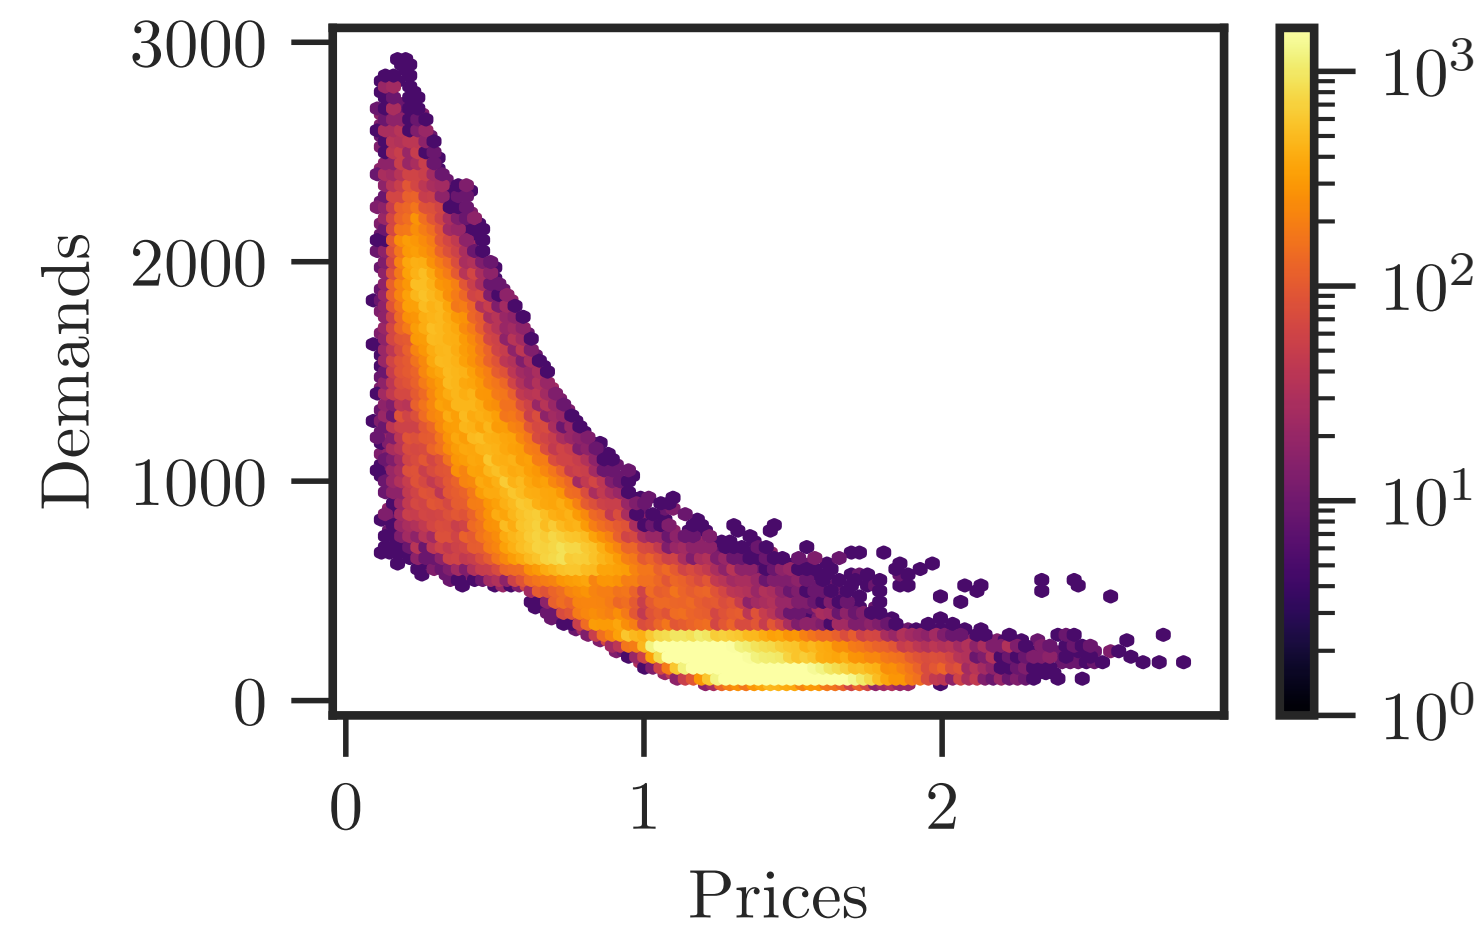

Stable Phase (S)

$$\sigma = -0.75$$

Unstable Phase (U)

$$\sigma = 0.2$$

Switching between goods - S phase

Switching between goods - U phase

What about the EC phase?

- Dynamical Switching here too.
- Bimodal supply demand distributions as well.

Why crises?

- Removal of agents fragilises the economy.
- (Surviving) Agents' profits reduce when other agents go bankrupt.
- Biased random walk leads to synchronized crisis waves. (Gualdi et al. PRL 114, 088701 (2015))

Conclusion

- Prototype ABM with budgetary constraints.
- Spontaneous speciation of goods.
- Three phases as a function of allowed debt :
 - Unstable Phase: No structure since agents can't adapt
 - Stable Phase: Speciation of goods and few bankruptcies
 - EC phase: Endogenous crises with waves of defaults.
- Debt is central to understand internal dynamics
- “Goldilocks” zone of debt where things are stable with low volatility

THANK YOU

Remaining questions

- Q1: Why switches ?

- Q2: Why crises?

Remaining questions

- Q1: Why switches ?
- A1: Failure of large buyer -> cascade of other failure -> rise in prices -> suppressed demand.
- Q2: Why crises?
